

## AMENDMENTS TO THE CLAIMS

1. (Previously presented) An optical disk device comprising:

irradiating means for irradiating a light beam onto a recordable optical disk having a wobbled track;

light receiving means for receiving the light reflected from the optical disk and generating an electric signal corresponding to the reflected light; and

wobble signal reproducing means for reproducing, from the electric signal generated by the light receiving means, a wobble signal corresponding to a wobble of the track, wherein at any given recording speed said wobble signal reproducing means reproduces the wobble signal within a period of irradiation of the light beam with a recording power and also reproduces the wobble signal within a period of irradiation of the light beam with a reproduction power.

2. (Original) The optical disk device according to claim 1, wherein said wobble signal reproducing means reproduces said wobble signal within the period of irradiation of the light beam with recording power, and also within a period where the reflected light is in a stable condition at a predetermined level after a pit is formed on the optical disk.

3-4. (Canceled)

5. (Previously presented) An optical disk device comprising:

a light source that irradiates a light beam of recording power and a light beam of reproduction power alternately onto a recordable optical disk having a wobbled track;

a photodetector having two light receiving surfaces divided in a radial direction of the optical disk, said photodetector receiving, on the two light receiving surfaces, the light reflected from the optical disk and generating a first and a second output signal, respectively;

sample-and-hold circuits that sample and hold the first and second output signals, respectively, during a period of the light beam of recording power;

a differentiator that determines a difference between two signals from said sample-hold circuits;

second sample-hold circuits that sample and hold the first and second output signals during a period of the light beam of reproduction power;

a second differentiator that determines a difference between two signals from said second sample-hold circuits,

wherein said wobble signal is reproduced on the basis of an output of said differentiator and an output of said second differentiator.

6. (Original) The optical disk device according to claim 5, wherein said sample-hold circuits, within the period of the light beam of recording power, sample the first and second output signals at the timing delayed by a predetermined period of time after the start of recording.

7. (Previously presented) The optical disk device according to claim 5, further comprising:

an adder that adds the output of said differentiator and an output of said second differentiator,

wherein the wobble signal is reproduced from an output of the adder.

8. (Previously presented) The optical disk device according to claim 5, further comprising:

a level adjusting circuit that equalizes the level of the signals outputted from the sample-hold circuits and the level of the signals outputted from said second sample-hold circuits.

9. (Previously presented) The optical disk device according to Claim 6, further comprising:

an adder that adds the output of said differentiator and an output of said second differentiator,

wherein the wobble signal is reproduced from an output of the adder.

10. (Original) The optical disk device according to claim 9, further comprising:

a level adjusting circuit that equalizes the level of the signals outputted from the sample-hold circuits and the level of the signals outputted from said second sample-hold circuits.

11. (Canceled)
